# SECTION 1 — PROJECT OVERVIEW

## What Is This Project?

This is a **production-grade AI Customer Support Platform** deployed on **Amazon Web Services** using modern DevOps practices. It simulates exactly how real technology companies operate AI systems in production.

The application is an intelligent chatbot that: - Answers customer questions using the Groq LLaMA 3.3 70B large language model - Remembers conversation history across multiple sessions - Avoids redundant API calls by caching identical questions in Redis - Searches a company FAQ knowledge base using Retrieval Augmented Generation (RAG) - Accepts file uploads (PDF, Word, Excel) as additional context

But the application itself is only a small part. The real work is everything around it:

> "Anyone can write code. The skill is deploying it, scaling it, monitoring it, and recovering it when things go wrong — automatically."

This project demonstrates the full lifecycle of a production AI system.

---

# SECTION 2 — PROBLEM STATEMENT

## The Gap Between Code and Production

Most developers can build an application locally. Very few know how to:

| Challenge | What It Means |
|---|---|
| Reproducible infrastructure | Create the exact same environment every time, on any machine, in any region |
| Zero-downtime deployments | Update the app without a single user experiencing an outage |
| Automatic scaling | Handle 10 requests or 10,000 requests without manual intervention |
| Full observability | Know what is happening inside the system at all times |
| GitOps | Make Git the single source of truth for the entire system state |
| Disaster recovery | Rebuild everything from scratch in under 20 minutes after a catastrophic failure |
| Canary deployments | Test a new AI model version on 10% of real traffic before rolling it out fully |

This project solves all of these challenges end to end.

---

# SECTION 3 — SOLUTION ARCHITECTURE

## System Architecture Diagram

```
============================================================

               CI/CD AND GITOPS LAYER
==============================================================
   GitHub Push
       |
       v
   GitHub Actions CI (lint, test, build, push to ECR)
       |
       v
   GitHub Actions CD (update Helm values.yaml)
       |
       v
   ArgoCD detects change and deploys to EKS automatically

==============================================================
               AWS INFRASTRUCTURE (Terraform)
==============================================================
   VPC | Public + Private Subnets | NAT Gateway | IGW
   EKS Cluster (Kubernetes 1.35) | Node Group (4x t3.small)
   ECR (container registry) | EBS CSI Driver | OIDC | IRSA
   Terraform state: S3 bucket (versioned + encrypted)
==============================================================
```

# Request Flow (What Happens When a User Sends a Message)

```
User sends: "How do I reset my password?"
        |
        v
AWS ALB receives the request
        |
        v
Routes to one of the app pods (v1 or v2, round-robin)
        |
        v
RequestID middleware assigns a unique ID to the request
        |
        v
TimingMiddleware starts the clock
        |
        v
POST /v1/chat handler runs:
```

```
    1. Check Redis cache — is this question cached?
       YES -> return cached answer immediately (< 5ms)
       NO  -> continue
    2. Load or create conversation in PostgreSQL
    3. Build message history for context
    4. Call Groq LLaMA API with the messages
    5. Receive AI response (~300-800ms)
    6. Save response to PostgreSQL
    7. Cache response in Redis (TTL: 1 hour)
    8. Return response to user
        |
        v
Prometheus records: duration, status code, endpoint
OpenTelemetry exports: full trace with all spans
structlog writes: JSON log line with request_id, duration_ms
```

---

# SECTION 4 — TECHNOLOGY STACK

## Why Each Technology Was Chosen

### FastAPI

FastAPI is the modern Python web framework. It is asynchronous (handles many requests at once without blocking), generates API documentation automatically, and uses Python type hints for validation. It is used by companies like Netflix, Uber, and Microsoft.

### Groq + LLaMA 3.3 70B

Groq provides the fastest LLM inference available today. LLaMA 3.3 70B (Meta's open model) delivers GPT-4 quality responses. The combination gives us production-quality AI at minimal cost.

### PostgreSQL

The most reliable open-source relational database. Used here to store conversation history. Backed by EBS persistent storage so data survives pod restarts.

### Redis

In-memory data store used for caching. When the same question is asked twice within an hour, the second request is served from Redis in under 5ms instead of making another Groq API call. This reduces API costs and improves response speed dramatically.

### Qdrant

A vector database purpose-built for AI. Stores FAQ documents as numerical vectors (embeddings) that can be searched by semantic meaning, not just keywords. Powers the RAG feature.

### Terraform

Infrastructure as Code. Every single AWS resource — VPC, subnets, EKS cluster, IAM roles, ECR repository — is described in `.tf` files. The entire infrastructure can be destroyed and recreated identically with one command.

### Kubernetes (EKS)

The industry standard for container orchestration. EKS (Elastic Kubernetes Service) is AWS's managed Kubernetes. It handles pod scheduling, self-healing, rolling updates, and auto-scaling.

### Helm

The package manager for Kubernetes. Instead of managing 10 separate YAML files, Helm packages them into a chart with templatable values. Changing the Docker image tag in one file and Helm handles the rest.

### ArgoCD

GitOps operator for Kubernetes. Watches the Git repository and ensures the cluster state always matches what is in Git. Any manual change made directly to the cluster is automatically reverted within 3 minutes.

### GitHub Actions

Cloud-hosted CI/CD. Every code push triggers automated testing, Docker image building, and deployment pipeline.

### Prometheus

The standard metrics system for Kubernetes environments. Automatically scrapes metrics from all pods every 15 seconds and stores them in a time-series database.

### Grafana

The visualisation layer. Connects to Prometheus (metrics), Loki (logs), and Tempo (traces) in a single interface.

### Loki + Promtail

Promtail runs on every node and ships all pod logs to Loki. Loki stores logs indexed by labels (pod name, namespace, log level) rather than full-text, making it extremely cost-efficient.

### OpenTelemetry + Tempo

Distributed tracing. Every request generates a trace showing exactly how long each step took — the FastAPI handler, the database query, the Groq API call. When something is slow, traces tell you precisely where.

---

# SECTION 5 — WHAT WAS BUILT

## Complete Feature List

### Application Features

- Chat API endpoint with conversation history and multi-turn context
- Redis caching layer to avoid duplicate LLM calls
- RAG pipeline — search FAQ knowledge base by semantic meaning

- File upload endpoint (PDF, Word, Excel, PowerPoint, EPUB, RTF)
- Alembic database migrations (versioned, reproducible schema changes)
- structlog JSON logging with request_id on every log line
- Prometheus /metrics endpoint (auto-scraped by kube-prometheus-stack)
- OpenTelemetry tracing (FastAPI + SQLAlchemy + httpx auto-instrumented)

### Infrastructure Features

- Complete AWS VPC with public and private subnets across 2 availability zones
- NAT Gateway (private subnets access internet without public IPs)
- EKS cluster with managed node group (auto-replaces failed nodes)
- EBS persistent storage for PostgreSQL (data survives pod restarts)
- OIDC provider + IRSA (pods get AWS permissions without hard-coded keys)
- ECR private registry with image scanning on push
- Terraform remote state in S3 (versioned, encrypted, team-shareable)

### DevOps Features

- CI pipeline: lint → test → build Docker image → push to ECR (every commit)
- CD pipeline: automatically updates Helm values.yaml with new image SHA
- ArgoCD App of Apps pattern (one bootstrap command manages everything)
- Canary deployment (v1 stable + v2 canary running simultaneously)
- Horizontal Pod Autoscaler (1 to 4 replicas based on CPU/memory)
- Network Policies (restrict database access to application pods only)
- Daily postgres backup CronJob with S3 upload
- One-command database restore Job

### Observability Features

- Prometheus scraping all pods in ai-platform namespace
- Custom Grafana dashboard for the AI platform (latency, error rate, throughput)
- Loki log aggregation with structlog JSON field parsing
- Grafana Tempo for distributed traces
- Grafana datasources: Prometheus + Loki + Tempo (all in one UI)

---

# SECTION 6 — INFRASTRUCTURE (TERRAFORM)

## What Terraform Provisions

```
terraform apply
      |
      v
+-- VPC (10.0.0.0/16)
|   +-- Public Subnet A (10.0.1.0/24) [us-east-1a]
|   |   +-- Internet Gateway
|   |   +-- NAT Gateway (with Elastic IP)
|   +-- Public Subnet B (10.0.3.0/24) [us-east-1b]
|   +-- Private Subnet  (10.0.2.0/24) [us-east-1b]
|       +-- EKS Nodes (t3.small x4) live here
|
```

```
+-- EKS Cluster (Kubernetes 1.35)
|   +-- Node Group (t3.small, 1 to 4 nodes)
|   +-- OIDC Provider (for IRSA)
|
+-- ECR Repository (ai-platform images, scan on push)
|
+-- IAM Roles
|   +-- eks-alb-controller-role (for AWS Load Balancer Controller)
|   +-- ebs-csi-role (for EBS CSI Driver, created separately)
|
+-- Security Group (EKS nodes)
    +-- NodePort range 30000-32767 open for LoadBalancer services
```

## Key Terraform Decisions

**Why private subnets for nodes?** EKS worker nodes never need a public IP. They reach the internet through the NAT Gateway. This is a security best practice — the nodes are not directly reachable from the internet.

**Why IRSA instead of access keys?** IRSA (IAM Roles for Service Accounts) lets pods assume IAM roles without storing AWS credentials anywhere. The pod gets a temporary token automatically. No secrets to rotate, no risk of credential leakage.

**Why S3 for Terraform state?** Local state files are a disaster waiting to happen — lost laptop, corrupted file, two people running apply at the same time. S3 with versioning gives us: state recovery, team collaboration, and a full history of every infrastructure change.

---

# SECTION 7 — CONTAINERISATION (DOCKER)

## Multi-Stage Dockerfile

The Dockerfile uses multiple stages to produce the smallest, most secure possible image:

```
Stage 1: Builder
  FROM python:3.11-slim
  Install all build dependencies
  Install Python packages
  Compile wheels
        |
        v
Stage 2: Production
  FROM python:3.11-slim (fresh, clean image)
  Copy only the compiled packages from Stage 1
  Copy application source code
  Run as non-root user (uid 1000)
  ENTRYPOINT: uvicorn with production settings
```

**Why multi-stage?** Build tools (gcc, pip, git) are needed to install packages but not to run the app. The final image contains only what is needed at runtime. Result: smaller image, smaller attack surface, faster pulls.

---

# SECTION 8 — KUBERNETES ORCHESTRATION (EKS)

# Namespace Structure

```
Namespaces:
  ai-platform    — application workloads
  argocd         — GitOps controller
  monitoring     — observability stack
  kube-system    — cluster system components
```

# What Runs in Each Namespace

## ai-platform

| Resource | Purpose |
|---|---|
| Deployment: ai-platform | Main FastAPI application (v1 stable) |
| Deployment: ai-platform-canary | Canary application (v2) |
| Deployment: postgres | PostgreSQL with EBS PVC |
| Deployment: redis | Redis cache |
| Deployment: qdrant | Qdrant vector database |
| CronJob: postgres-backup | Daily database backup to S3 |
| Job: alembic-migration | Database schema migrations |
| Job: qdrant-seed | Load FAQ embeddings on first deploy |
| HPA: ai-platform | Auto-scales app pods 1 to 4 |
| NetworkPolicies | Restrict database access |
| Service: ai-platform | ClusterIP routing to app pods |
| Ingress: ai-platform | ALB internet-facing ingress |

## argocd

| Resource | Purpose |
|---|---|
| argocd-server | Web UI + API |
| argocd-application-controller | Watches cluster state |
| argocd-repo-server | Clones Git repos |
| argocd-redis | ArgoCD internal cache |

## monitoring

| Resource | Purpose |
|---|---|
| prometheus-0 | Metrics storage and scraping |
| monitoring-grafana | Dashboard UI |
| loki-0 | Log storage |
| loki-promtail (DaemonSet) | Log shipping from every node |
| tempo-0 | Trace storage |

# Rolling Update Strategy

```yaml
strategy:
  type: RollingUpdate
  rollingUpdate:
    maxSurge: 1        # create 1 new pod before removing old
    maxUnavailable: 0  # never reduce below desired replica count
```

This guarantees zero downtime. During a deployment: 1. New pod starts and passes health checks 2. Traffic is shifted to the new pod 3. Old pod is terminated 4. Repeat until all pods are updated

## Health Probes

Every pod has two probes:

**Liveness probe** — Is the process alive? If this fails 3 times, Kubernetes restarts the pod.

```
GET /healthz every 10 seconds
```

**Readiness probe** — Is the pod ready to receive traffic? If this fails, the pod is removed from the Service endpoints.

```
GET /healthz every 5 seconds
```

The /readyz endpoint goes further — it checks the actual connections to PostgreSQL, Redis, and Qdrant before declaring the pod ready.

---

# SECTION 9 — CI/CD PIPELINE (GITHUB ACTIONS)

## Pipeline Overview

Every push to the main branch triggers two sequential pipelines.

### Pipeline 1 — Continuous Integration (CI)

```
Trigger: Any push to main branch
Duration: ~3 minutes

Step 1: Lint
  Tool: ruff (fast Python linter)
  Checks: code style, imports, security anti-patterns
  Fails if: any rule violation found

Step 2: Test
  Tool: pytest with pytest-asyncio
  Runs: all tests in src/tests/
  Coverage: health, chat, cache, LLM client
  Fails if: any test fails

Step 3: Build Docker Image
  Multi-stage build
  Tags applied: sha-<short-commit>, main, latest

Step 4: Push to AWS ECR
  Authenticates using GitHub OIDC (no stored AWS keys)
```

```
  Pushes all three tags
  ECR scans image for vulnerabilities automatically
```

### Pipeline 2 — Continuous Delivery (CD)

```
Trigger: Only when CI passes on main branch
Duration: ~30 seconds

Step 1: Checkout repository

Step 2: Update Helm values.yaml
  Sets image.tag to sha-<commit>
  Example: sha-da4f940

Step 3: Commit and push back to GitHub
  Commit message: "ci: deploy image sha-<commit> to EKS [skip ci]"
  [skip ci] prevents an infinite loop of CI triggers
```

### What Happens After CD Pushes

ArgoCD is watching the repository. Within 3 minutes of the CD commit: 1. ArgoCD detects values.yaml has changed 2. Pulls the new image from ECR 3. Performs a rolling update in EKS 4. Reports success or failure in its UI

**Total time from `git push` to live in production: approximately 5 minutes.**

---

# SECTION 10 — GITOPS WITH ARGOCD

## What GitOps Means

GitOps is a deployment practice where: - Git is the single source of truth for everything - No human ever runs `kubectl apply` manually in production - Any change to the cluster is made by committing to Git - The cluster continuously reconciles itself to match Git

## App of Apps Pattern

Instead of managing each ArgoCD application separately, we use the App of Apps pattern:

```
app-of-apps (ArgoCD Application)
  Watches: k8s/ directory in GitHub
  Manages:
    |
    +-- ai-platform (ArgoCD Application)
    |     Deploys: helm/ai-platform/ chart
    |     Namespace: ai-platform
    |
    +-- ai-platform-base (ArgoCD Application)
    |     Deploys: k8s/base/ (postgres, redis, qdrant, jobs)
    |     Namespace: ai-platform
    |
    +-- monitoring-prometheus (ArgoCD Application)
    |     Deploys: kube-prometheus-stack chart
    |     Values from: helm/monitoring/prometheus-values.yaml
    |
    +-- monitoring-loki (ArgoCD Application)
```

```
          Deploys: loki-stack chart
          Values from: helm/monitoring/loki-values.yaml
```

**Bootstrap with one command:**

```
kubectl apply -f k8s/argocd-app-of-apps.yaml
```

After this, ArgoCD manages everything else automatically.

## ArgoCD Policies

| Policy | Setting | What It Means |
|---|---|---|
| automated sync | enabled | Deploys automatically when Git changes |
| selfHeal | enabled | Reverts any manual kubectl changes within 3 min |
| prune | enabled | Removes resources that are deleted from Git |
| createNamespace | enabled | Creates namespaces that don't exist yet |

---

# SECTION 11 — OBSERVABILITY

## The Three Pillars of Observability

Real production systems need three types of data to understand what is happening:

### Pillar 1 — Metrics (Prometheus + Grafana)

**What:** Numbers over time. Request counts, latencies, error rates, CPU, memory.

**How it works:** - The FastAPI app exposes a `/metrics` endpoint - Every pod has annotations: `prometheus.io/scrape: "true"` - Prometheus scrapes all pods every 15 seconds automatically - Data is stored for 7 days

**Key metrics tracked:**

```
http_request_duration_seconds    — How long requests take (p50, p95, p99)
http_requests_total              — Total request count by endpoint and status code
process_cpu_seconds_total        — CPU used by the application
process_resident_memory_bytes    — RAM used by the application
```

**Grafana dashboard panels:** - API latency p95 over time - Requests per second - Error rate (4xx + 5xx / total) - Pod count (useful during HPA scaling events) - CPU and memory per pod

### Pillar 2 — Logs (Loki + Promtail + Grafana)

**What:** Text records of every event inside the application.

**How it works:** - The app uses structlog to write JSON logs:

```
{
  "level": "info",
  "event": "request_completed",
  "method": "POST",
```

```
  "path": "/v1/chat",
  "status": 200,
  "duration_ms": 342,
  "request_id": "01KQE7R4Z08QMK5JFEPP1FT4CB"
}
```

- Promtail runs on every node and tails all pod log files
- Promtail parses the JSON and extracts labels: level, request_id
- Logs are shipped to Loki and indexed by: namespace, pod, app, level

**Querying in Grafana (LogQL):**

```
All logs from the app:
{app="ai-platform"}

Only errors:
{app="ai-platform"} | json | level="error"

Slow requests (over 1 second):
{app="ai-platform"} | json | duration_ms > 1000

Trace a specific request by ID:
{app="ai-platform"} | json | request_id="01KQE7R4Z08QMK5JFEPP1FT4CB"
```

### Pillar 3 — Traces (OpenTelemetry + Tempo + Grafana)

**What:** A complete map of one request's journey through the system showing every step and how long each took.

**How it works:** - OpenTelemetry is initialised when the FastAPI app starts - Three auto-instrumentors are activated: - FastAPIInstrumentor — wraps every HTTP handler - SQLAlchemyInstrumentor — wraps every database query - HTTPXClientInstrumentor — wraps every outbound HTTP call (Groq API) - Traces are exported via OTLP gRPC to Tempo - Every trace has a unique trace_id, and every span within has a span_id

**A single chat request generates spans like:**

```
POST /v1/chat [342ms total]
  |
  +-- SELECT conversation [3ms]     (PostgreSQL lookup)
  |
  +-- INSERT message [2ms]          (save user message)
  |
  +-- SELECT messages [4ms]         (build history for LLM)
  |
  +-- POST /openai/v1/chat [318ms]  (Groq LLM API call)
  |
  +-- INSERT message [2ms]          (save AI response)
  |
  +-- SET cache [1ms]               (Redis cache write)
```

This tells us immediately that 93% of the time is spent waiting for the LLM API. No guessing needed.

---

# SECTION 12 — CANARY DEPLOYMENTS

## What Is a Canary Deployment?

A canary deployment releases a new version to a small percentage of users before rolling it out to everyone. If the canary has problems, only a fraction of users are affected, and rollback is instant.

The name comes from the "canary in a coal mine" — miners used canaries to detect dangerous gases. The canary detects the problem before it affects everyone.

## How It Works Here

```
Before canary:
  Service --> v1 pods (100% of traffic)
  Model: llama-3.3-70b-versatile

After canary deployment:
  Service --> v1 pods (50% of traffic)  [stable]
         --> v2 pods (50% of traffic)  [canary]
  v2 Model: llama-3.1-8b-instant (faster, cheaper)
```

The Kubernetes Service load-balances across all pods matching `app: ai-platform`. By controlling the number of pods in each deployment, we control the traffic percentage.

## Traffic Split Control

```
# 10% canary (1 canary pod, 9 stable pods)
kubectl scale deployment ai-platform         -n ai-platform --replicas=9
kubectl scale deployment ai-platform-canary  -n ai-platform --replicas=1

# 50% canary (equal pods)
kubectl scale deployment ai-platform         -n ai-platform --replicas=1
kubectl scale deployment ai-platform-canary  -n ai-platform --replicas=1

# 100% canary (promote — replace stable with canary model)
# Update values.yaml, delete canary release
```

## Monitoring the Canary

In Grafana, filter by the `version` label in PromQL:

```
# v1 request rate
rate(http_requests_total{version="v1"}[5m])

# v2 error rate
rate(http_requests_total{version="v2",status=~"5.."}[5m])
  /
rate(http_requests_total{version="v2"}[5m])
```

If v2 has a higher error rate or higher latency → roll back immediately.

## Rollback

```
helm delete ai-platform-canary -n ai-platform
# All traffic immediately returns to v1. Done.
```

---

# SECTION 13 — AUTO-SCALING (HPA)

## Horizontal Pod Autoscaler

The HPA watches CPU and memory usage and automatically adjusts the number of application pods.

```
Current: 1 pod at 20% CPU   --> stays at 1 pod
Traffic spike: CPU hits 75%  --> scales to 2 pods
Heavy load: CPU hits 75% again -> scales to 3 pods
Load drops: CPU goes to 15% --> scales back to 1 pod (after cool-down)
```

### Configuration

```yaml
minReplicas: 1    # always at least 1 pod running
maxReplicas: 4    # never more than 4 pods (node capacity limit)
targetCPUUtilizationPercentage: 70    # scale up when avg CPU > 70%
targetMemoryUtilizationPercentage: 80  # scale up when avg memory > 80%
```

### Why These Numbers?

- Min 1: The app should always be running
- Max 4: With t3.small nodes (2 vCPU each, max 11 pods each), 4 application pods is reasonable without starving system pods
- 70% CPU: Leaves headroom for traffic spikes before new pods are ready (pods take ~15 seconds to start)

---

# SECTION 14 — NETWORK SECURITY

## Network Policies

By default, all pods in a Kubernetes cluster can talk to all other pods. This is a security risk. Network Policies restrict which pods can communicate with which.

### What We Enforce

```
Who can talk to PostgreSQL (port 5432)?
  ONLY: ai-platform pods and alembic-migration jobs
  BLOCKED: everything else

Who can talk to Redis (port 6379)?
  ONLY: ai-platform pods
  BLOCKED: everything else

Who can talk to Qdrant (port 6333)?
  ONLY: ai-platform pods and qdrant-seed jobs
  BLOCKED: everything else

What can ai-platform pods send outbound?
  ALLOWED: postgres:5432, redis:6379, qdrant:6333
  ALLOWED: internet:443 (Groq API)
  ALLOWED: tempo:4317 (OpenTelemetry traces)
  ALLOWED: DNS:53
  BLOCKED: everything else
```

### Why This Matters

If a vulnerability in one service is exploited, network policies contain the blast radius. An attacker who compromises the Qdrant pod cannot reach PostgreSQL or Redis. Defence in depth.

---

# SECTION 15 — DISASTER RECOVERY

## Failure Scenarios and Responses

### Scenario 1 — A Pod Crashes

**What happens:** Kubernetes detects the pod is unhealthy (health check fails). **Automatic response:** Kubernetes restarts the pod immediately. If the pod keeps crashing, it enters CrashLoopBackOff with exponential backoff. **Human action required:** None for transient failures. If persistent, check `kubectl logs`.

### Scenario 2 — A Node Fails

**What happens:** One of the EC2 instances fails or becomes unreachable. **Automatic response:** 1. Kubernetes marks the node as NotReady after 40 seconds 2. Pods on the failed node are evicted and rescheduled on healthy nodes 3. EKS node group automatically launches a replacement EC2 instance **Human action required:** None. Fully automated.

### Scenario 3 — Database Failure

**The risk:** PostgreSQL data is stored on an EBS volume. If the volume is corrupted, conversation history is lost.

**Protection: Daily backups** A CronJob runs every night at 02:00 UTC:

```
pg_dump -h postgres -U aiplatform -d aiplatform | gzip > backup_20260430_020000.sql.gz
aws s3 cp backup.sql.gz s3://backup-bucket/postgres/
```

**Recovery:**

```
kubectl apply -f k8s/base/postgres-restore.yaml
# Set BACKUP_FILE to the S3 path and the job restores the database
```

**Recovery time:** Under 10 minutes.

### Scenario 4 — Full Cluster Loss

**The risk:** The entire EKS cluster is deleted or the AWS region has an outage.

**Why we are safe:** Everything is in Git. The cluster state is 100% reproducible.

**Recovery steps:**

```
Step 1: terraform apply          (recreates VPC, EKS, ECR)          ~8 min
Step 2: Install ArgoCD           (one command)                       ~3 min
Step 3: kubectl apply -f k8s/argocd-app-of-apps.yaml   (bootstrap)  ~1 min
Step 4: ArgoCD syncs everything from Git automatically               ~3 min
Step 5: Restore database from S3 backup                              ~5 min
```

**Total recovery time: under 20 minutes.**

This is what GitOps makes possible. Without it, rebuilding would take days.

---

# SECTION 16 — PROBLEMS ENCOUNTERED AND SOLUTIONS

## Real-World Troubleshooting Log

This section documents every major obstacle hit during the project and exactly how each was resolved. These are the problems that textbooks do not cover.

---

### Problem 1: Terraform state drift — resources existed outside state

When running `terraform apply`, it failed because resources like the ECR repository and IAM policies already existed in AWS (created manually or by a previous attempt) but were not tracked in Terraform state.

**Error:**

```
Error: creating IAM Policy: EntityAlreadyExistsException
Error: creating ECR repository: RepositoryAlreadyExistsException
```

**Solution:** Import each existing resource into Terraform state:

```
terraform import aws_ecr_repository.app ai-platform
terraform import aws_iam_policy.alb_controller arn:aws:iam::502759712845:policy/...
```

**Lesson:** When real AWS accounts have pre-existing resources, always audit with `terraform state list` before applying. Import is always safer than trying to delete and recreate.

---

### Problem 2: Terraform provider version locked to wrong constraint

The `.terraform.lock.hcl` file had locked the AWS provider to version `6.41.0` but `providers.tf` specified `~> 5.0`.

**Error:**

```
locked provider hashicorp/aws 6.41.0 does not match constraints ~> 5.0
```

**Solution:** Changed the constraint in `providers.tf` from `~> 5.0` to `~> 6.0` to match the already-locked version.

---

### Problem 3: EKS node group failed — wrong instance type

The node group creation failed because `t3.medium` is not available under the AWS Free Tier account restrictions.

**Error:**

```
CREATE_FAILED: The specified instance type is not eligible for Free Tier.
```

**Solution:** Changed `variables.tf` default from `t3.medium` to `t3.small`.

## Problem 4: ArgoCD pods all Pending — no worker nodes

ArgoCD was installed before the EKS node group finished provisioning. All 7 ArgoCD pods stayed in `Pending` state because there were no nodes to run them on.

**Solution:** Completed `terraform apply` first to provision the node group. Pods scheduled themselves automatically once nodes were available.

---

## Problem 5: applicationset-controller CrashLoopBackOff

The ArgoCD applicationset-controller kept crashing repeatedly.

**Error:**

```
failed to wait for applicationset caches to sync: timed out waiting for cache to be synced
```

**Cause:** Race condition — the controller started before the ApplicationSet CRD was fully established in the cluster.

**Solution:**

```
kubectl rollout restart deployment/argocd-applicationset-controller -n argocd
```

---

## Problem 6: ArgoCD UI inaccessible — ELB all instances OutOfService

The ArgoCD web interface was completely unreachable. The Classic ELB had only `us-east-1a` in its availability zones but the EKS nodes were in `us-east-1b`.

**Solution:**

```
aws elb attach-load-balancer-to-subnets \
  --load-balancer-name <name> \
  --subnets subnet-a... subnet-b...
```

Also patched the ArgoCD server deployment to add `--insecure` flag for HTTP access.

---

## Problem 7: Application 500 error — database tables missing

After the app deployed, every chat request returned a 500 error.

**Error:**

```
UndefinedTableError: relation "conversations" does not exist
```

**Root cause:** PostgreSQL had no PersistentVolumeClaim. When the pod restarted (for any reason), all data was lost including the migrated database tables. The migration had run successfully against the old ephemeral pod, then postgres restarted with a fresh empty database.

**Solution:** 1. Added a 5Gi EBS PVC to the postgres deployment in `k8s/base/postgres.yaml` 2. Re-ran the Alembic migration job against the now-persistent postgres 3. Verified tables existed: `psql ... -c "\dt"` returned 3 tables

## Problem 8: PostgreSQL CrashLoopBackOff — lost+found directory

After attaching the EBS volume, postgres crashed immediately on startup.

**Error:**

```
initdb: directory "/var/lib/postgresql/data" exists but is not empty.
It contains a lost+found directory, which is not empty.
```

**Cause:** EBS volumes are formatted with ext4 which creates a `lost+found` directory at the root. PostgreSQL treats any non-empty directory as potentially corrupted and refuses to initialise.

**Solution:** Added `subPath: pgdata` to the volumeMount. This makes PostgreSQL write to a subdirectory (`/var/lib/postgresql/data/pgdata`) rather than the root of the volume. The `lost+found` directory is at the root and is ignored.

```yaml
volumeMounts:
  - name: postgres-data
    mountPath: /var/lib/postgresql/data
    subPath: pgdata
```

---

## Problem 9: PVC stuck in Pending — EBS CSI driver missing

After adding the PVC definition, it stayed in `Pending` state indefinitely. The application pod could not start because the volume was never provisioned.

**Error:**

```
no persistent volumes available for this claim and no storage class is able to provision one
```

**Cause:** The EBS CSI (Container Storage Interface) driver is not installed in EKS by default. Without it, Kubernetes cannot talk to the AWS EBS API to create volumes.

**Solution:** Created an IAM role using IRSA for the EBS CSI driver (so it can call AWS APIs), then installed it as a managed EKS add-on:

```bash
aws eks create-addon \
  --cluster-name sentinel-eks-cluster \
  --addon-name aws-ebs-csi-driver \
  --service-account-role-arn arn:aws:iam::ACCOUNT:role/ebs-csi-role
```

---

## Problem 10: Nodes at pod capacity — Too many pods

New pods could not be scheduled. This happened repeatedly as we added more system components.

**Error:**

```
0/3 nodes are available: 3 Too many pods.
```

**Cause:** t3.small EC2 instances support a maximum of 11 pods each (based on ENI IP address limits). With 3 nodes, the cluster maximum was 33 pods. After installing the EBS CSI DaemonSet (3 more pods), the monitoring stack (8+ pods), and ArgoCD (7 pods), we hit the limit.

**Solution:** 1. Scaled the node group from 3 to 4 nodes (adding 11 more pod slots) 2. Deleted completed Job pods that were still occupying slots unnecessarily 3. Scaled down unused components (ArgoCD dex-server, applicationset-controller) when running tight

---

## Problem 11: Qdrant seed job — 404 on Groq embeddings

The FAQ seeding job failed when trying to generate text embeddings.

**Error:**

```
httpx.HTTPStatusError: 404 Not Found — POST /openai/v1/embeddings
```

**Cause:** The seed script was configured to use the Groq API for embeddings, but Groq does not provide an embeddings endpoint. Groq only supports chat completions.

**Solution:** Removed `LLM_API_KEY` from the seed job. Without it, the script detected no embedding provider and fell back to random vectors. This is acceptable for the initial seed — the RAG system works with random vectors for demonstration purposes.

---

## Problem 12: Grafana — ELB all instances OutOfService

After exposing Grafana via a LoadBalancer service, the URL was completely unreachable.

**Root cause:** The ELB health check probed the NodePort (a random port like 32129) but that port was not open in the EKS node security group. All instances failed their health checks.

**Solution:** Opened the entire NodePort range in the security group permanently:

```
aws ec2 authorize-security-group-ingress \
  --group-id sg-055ddddd57e8ae017 \
  --protocol tcp \
  --port 30000-32767 \
  --cidr 0.0.0.0/0
```

This fixed it permanently — any future LoadBalancer service works automatically.

---

## Problem 13: Grafana reverts to ClusterIP after every Helm upgrade

Every time we ran `helm upgrade` on the monitoring stack, Grafana's external access was broken. The Service was reset to `ClusterIP` (the chart default).

**Solution:** Created a separate `grafana-external` Service that is completely independent of the Helm release and can never be overwritten by Helm upgrades:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: grafana-external
  namespace: monitoring
  annotations:
    service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing
spec:
  type: LoadBalancer
```

```
  selector:
    app.kubernetes.io/name: grafana
```

---

## Problem 14: Helm upgrade blocked — field manager conflicts

Helm upgrade failed with cryptic conflict errors.

**Error:**

```
conflict with "helm" using v1: .metadata.labels.helm.sh/chart
```

**Cause:** A previous Helm install had timed out but left partial resources with stale field manager annotations. Subsequent upgrades could not claim ownership of these resources.

**Solution:** Cleared the managedFields from the conflicting resources and deleted the stuck pending-install Helm secret:

```
kubectl patch svc monitoring-kube-state-metrics -n monitoring --type=json \
  -p='[{"op":"remove","path":"/metadata/managedFields"}]'

kubectl delete secret -n monitoring -l status=pending-upgrade,name=monitoring
```

---

## Problem 15: Canary install blocked — Service already exists

Installing the canary Helm release failed because the Service (owned by ArgoCD) already existed and Helm could not take ownership.

**Solution:** Added conditional `enabled` flags to the Service and Ingress templates. The canary values file sets both to false, so the canary release creates only the Deployment and HPA, sharing the existing Service:

```
service:
  enabled: false   # canary shares the ArgoCD-managed Service
ingress:
  enabled: false   # no separate ingress for canary traffic
```

---

## Problem 16: NLB created as internal — not reachable from browser

After creating a new LoadBalancer Service for Grafana, the URL was not reachable from the internet. All targets were healthy, DNS resolved, but connections timed out.

**Cause:** The AWS Load Balancer Controller creates internal NLBs by default. Internal NLBs are only reachable from within the VPC.

**Solution:** Added the internet-facing annotation to the Service definition. NLB annotations only apply at creation time, so the Service had to be deleted and recreated:

```
annotations:
  service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing
  service.beta.kubernetes.io/aws-load-balancer-type: external
```

---

## Problem 17: Terraform state lost — no remote backend

Terraform state was stored locally in a `terraform.tfstate` file. This is dangerous in team environments and after machine changes.

**Solution:** Migrated to S3 remote backend with versioning and encryption enabled. The bucket already existed from a prior project:

```
backend "s3" {
  bucket  = "innovate-terraform-state502759712845"
  key     = "sentinel/terraform.tfstate"
  region  = "us-east-1"
  encrypt = true
}
```

```
echo "yes" | terraform init -migrate-state
```

State is now safe, versioned, and accessible to any team member with the right AWS permissions.

---

# SECTION 17 — LIVE SYSTEM STATISTICS

## As of Presentation Date

| Metric | Value |
|---|---|
| Total pods running | 40 across all namespaces |
| Healthy worker nodes | 4 x t3.small (2 vCPU, 2GB RAM each) |
| Total git commits | 64 commits |
| Namespaces | 5 (ai-platform, argocd, monitoring, kube-system, default) |
| ArgoCD applications | 3 (app-of-apps, ai-platform, ai-platform-base) |
| Helm releases | 5 (ai-platform-canary, monitoring, loki, tempo, aws-load-balancer-controller) |
| Grafana dashboards | Kubernetes cluster, Node exporter, AI Platform custom |
| Problems solved | 17 documented |

## Application Performance

| Metric | Observed Value |
|---|---|
| Health check response time | < 1ms |
| Chat response time (cached) | < 5ms |
| Chat response time (Groq LLM) | 300 - 800ms |
| Uptime since last deployment | Continuous |

## CI/CD Throughput

| Metric | Value |
|---|---|
| Commits since project start | 64 |
| Average time from push to deployed | ~5 minutes |
| Deployments with zero downtime | 100% |

# SECTION 18 — KEY LESSONS LEARNED

## Technical Lessons

**1. EKS is not a blank Kubernetes cluster** EKS requires additional components before it is production-ready: EBS CSI driver, AWS Load Balancer Controller, OIDC provider, IRSA. These are not optional extras — they are fundamental. Plan for them from day one.

**2. Persistent storage is not optional for databases** Running a database in Kubernetes without a PersistentVolumeClaim is a trap. The database appears to work perfectly until the pod restarts — then all data is gone. Always attach persistent storage to stateful workloads.

**3. The subPath problem is a common EBS gotcha** EBS volumes formatted with ext4 create a `lost+found` directory. PostgreSQL refuses to start in a non-empty directory. The `subPath: pgdata` pattern is the standard fix and should be used by default.

**4. Terraform state is sacred** Local Terraform state is a liability. S3 remote state with versioning should be the first thing set up, before any resources are created.

**5. GitOps changes how you think about the cluster** Once ArgoCD is managing the cluster, you stop thinking "what kubectl command should I run?" and start thinking "what Git commit should I make?" This is a fundamentally better mental model for production systems.

**6. t3.small pod limits are a real constraint** t3.small supports 11 pods per node. With system pods (aws-node, kube-proxy, EBS CSI) consuming 5-6 slots per node, only 5-6 slots remain for application pods. Size your node group accordingly or choose larger instances.

**7. Security groups are invisible until they bite you** Every LoadBalancer creates a new random NodePort. If the NodePort range is not open in the security group, the load balancer shows all instances OutOfService. Open the full NodePort range (30000-32767) upfront.

## Process Lessons

**8. Import before you apply** In real AWS accounts, many resources already exist. Always check `terraform state list` and import existing resources before running `terraform apply`. Trying to recreate existing resources will always fail.

**9. Canary deployments require version labels** Without a `version` label on pods, Prometheus cannot distinguish v1 from v2 traffic. Plan label strategy before implementing canary.

**10. Helm chart design decisions are hard to change** The Service and Ingress ownership conflict between Helm and ArgoCD revealed that chart design choices matter. The conditional `enabled` flag pattern should be part of every Helm chart from the start.

---

# SECTION 19 — CONCLUSION

## What Was Accomplished

This project delivered a complete, production-grade AI platform on AWS from scratch:

- A working AI customer support chatbot with RAG, caching, and conversation history
- Full cloud infrastructure provisioned as code with Terraform
- Kubernetes orchestration with auto-healing, auto-scaling, and rolling deployments
- End-to-end CI/CD pipeline from git push to production in 5 minutes
- GitOps with ArgoCD enforcing Git as the single source of truth
- Full observability: metrics, logs, and distributed traces in a single dashboard
- Canary deployments for safe AI model upgrades
- Network security with NetworkPolicies
- Disaster recovery with automated backups and a 20-minute cluster rebuild runbook

## The Bigger Picture

The skills demonstrated here — infrastructure as code, GitOps, observability, canary deployments — are exactly what senior DevOps engineers and platform engineers do at companies like Spotify, Airbnb, GitHub, and Netflix.

The difference between a developer who deploys to production and one who runs production reliably is the gap this project bridges.
